ASSIGNMENT 1

PAYMENT CALCULATOR FOR A VILLAGE MILK CO-OPERATIVE

Task 2: Explore Values and Data Types

Objective: To explore Python values and identify their data types for the milk payment calculator.

Explanation:

Python provides different data types to store different kinds of information. In the milk payment calculator, farmer ID and shift are strings, milk quantity and quality percentages are floating-point numbers, and the payment status can be represented using a Boolean value.

Variable	Example value	Data type
farmer_id	"F001"	String (str)
litres	10.5	Float (float)
fat	4.0	Float (float)
snf	8.7	Float (float)
shift	"Morning"	String (str)
paid	True	Boolean (bool)

Observation: The `type()` function identifies the data type of each variable. Strings store text, floats store decimal numbers, and Boolean values represent `True` or `False`.

Conclusion: Understanding data types helps us choose appropriate variables and perform calculations correctly. For accurate financial calculations, the final payment calculator can use Python's `Decimal` type for monetary values.
